

most unsuccessful familings are planed. Space Λ, performs a controlled familing in the oceans.

Objectives

Perform exploratory Data Analysis and determine Training Labels

- · create a column for the class
- · Standardize the data
- · Split into training data and test data

-Find best Hyperparameter for SVM, Classification Trees and Logistic Regression

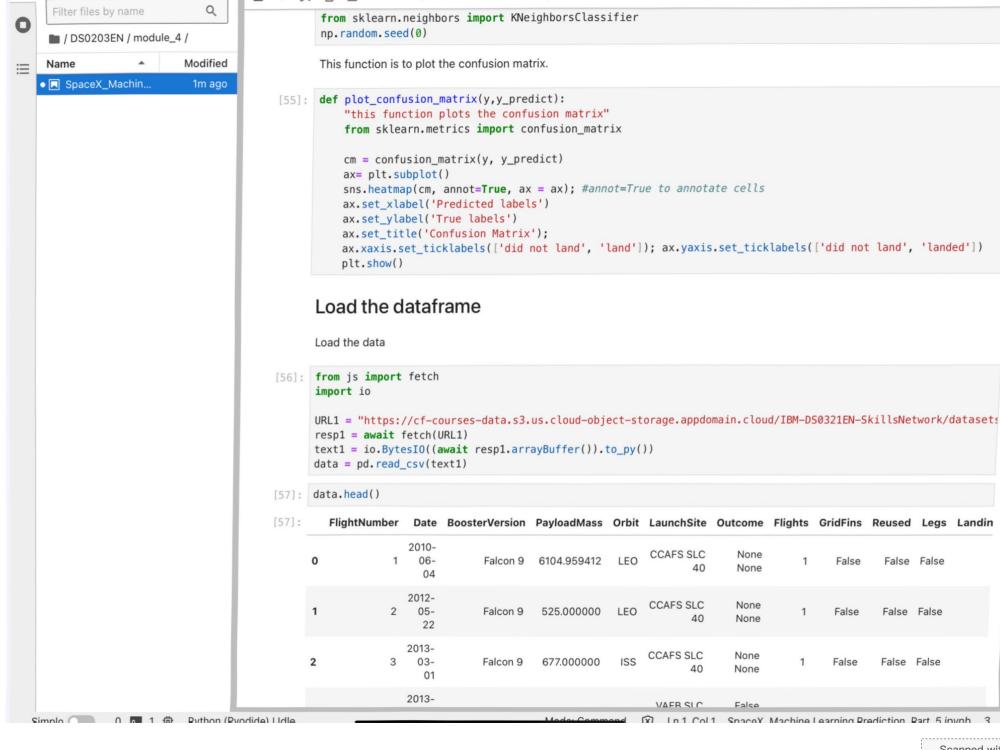

Find the method performs best using test data

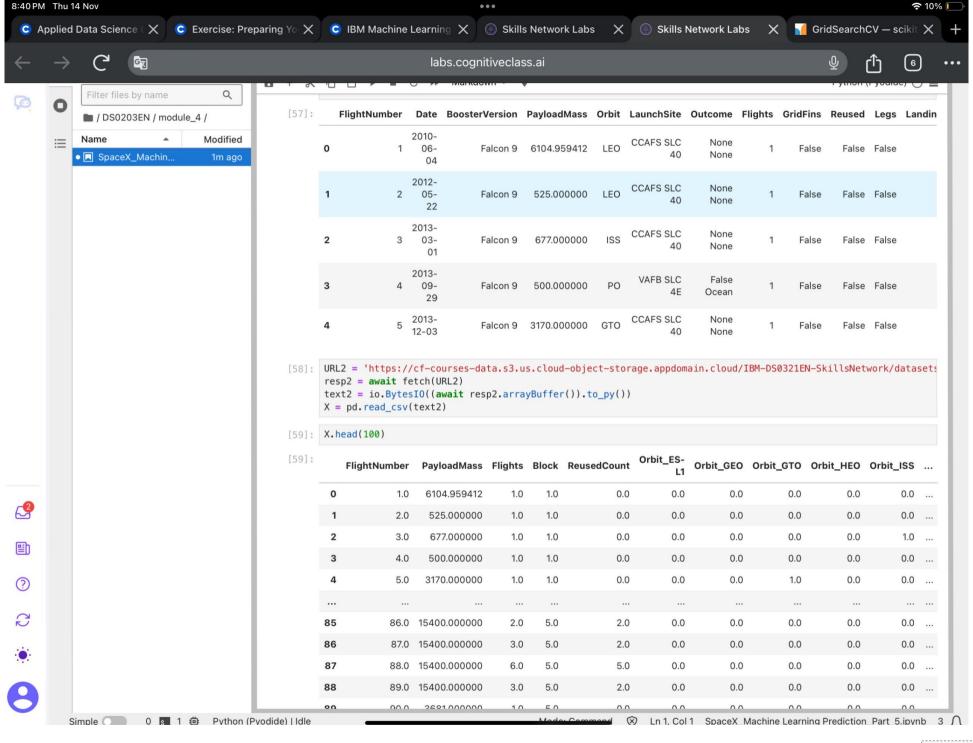

Import Libraries and Define Auxiliary Functions

```
import piplite
await piplite.install(['numpy'])
await piplite.install(['pandas'])
await piplite.install(['seaborn'])
```

We will import the following libraries for the lab

```
[94]: # Pandas is a software library written for the Python programming language for data manipulation and analysis.
      import pandas as pd
      # NumPy is a library for the Python programming language, adding support for large, multi-dimensional arrays a
      import numpy as np
      # Matplotlib is a plotting library for python and pyplot gives us a MatLab like plotting framework. We will us
      import matplotlib.pyplot as plt
      #Seaborn is a Python data visualization library based on matplotlib. It provides a high-level interface for di
      import seaborn as sns
      # Preprocessing allows us to standarsize our data
      from sklearn import preprocessing
      # Allows us to split our data into training and testing data
      from sklearn.model_selection import train_test_split
      # Allows us to test parameters of classification algorithms and find the best one
      from sklearn.model_selection import GridSearchCV
      # Logistic Regression classification algorithm
      from sklearn.linear_model import LogisticRegression
      # Support Vector Machine classification algorithm
      from sklearn.svm import SVC
      # Decision Tree classification algorithm
      from sklearn.tree import DecisionTreeClassifier
      # K Nearest Neighbors classification algorithm
```

90 rows x 83 columns

TASK 1

Create a NumPy array from the column Class in data, by applying the method to_numpy() then assign it to the variable Y, make sure the output is a Pandas series (only one bracket df['name of column']).

```
[60]: Y=data['Class'].to_numpy()
[60]: array([0, 0, 0, 0, 0, 0, 1, 1, 0, 0, 0, 0, 1, 0, 0, 0, 1, 0, 0, 1, 1, 1,
             1, 1, 0, 1, 1, 0, 1, 1, 0, 1, 1, 1, 0, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1,
             1, 0, 0, 0, 1, 1, 0, 0, 1, 1, 1, 1, 1, 1, 1, 0, 0, 1, 1, 1, 1, 1,
             1, 0, 1, 1, 1, 1, 0, 1, 0, 1, 0, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1,
             1, 1], dtype=int64)
```

TASK 2

Standardize the data in X then reassign it to the variable X using the transform provided below.

```
[61]: # students get this
      transform = preprocessing.StandardScaler()
      X=transform.fit_transform(X)
```

We split the data into training and testing data using the function train_test_split . The training data is divided into validation data, a second set used for training data; then the models are trained and hyperparameters are selected using the function GridSearchCV.

TASK 3

Use the function train_test_split to split the data X and Y into training and test data. Set the parameter test_size to 0.2 and random_state to 2. The training data and test data should be assigned to the following labels.

```
X_train, X_test, Y_train, Y_test
```

```
[62]: X train, X test, Y train, Y test = train_test_split(X, Y, test_size=0.2, random_state=2)
```

we can see we only have 18 test samples.
